ABSTRACT

Factors influencing the Compliance of Women Age 50-69 Years
With Breast Cancer Screening:
A Church Based Study.

Yvonne Lillian Bent-Williams

Breast cancer is the leading cause of cancer deaths in Jamaican women, the highest occurrence of breast cancer falls within the age group 55-64 years. This study sought to determine the compliance of women age 50-69 years with methods of early detection of breast cancer and the factors that affect non-compliance.

A cross sectional study was done among women age 50-69 years in Kingston and St. Andrew. Five Christian denominations were randomly selected and then one church was randomly selected from each denomination. Self-administered questionnaires were used as data collecting instruments.

Knowledgeable about breast cancer risk factors and screening methods was higher among persons with a higher level of education and among those who received medical care at private facilities. Compliance with breast self examination and
clinical breast examination were high (88% & 75% respectively) while compliance with mammography was low (39%). Significant factors, which influence breast cancer screening compliance, were educational background, income level, obtaining medical care from a private facility and having health insurance.

There was inadequate adherence with breast cancer screening guidelines in this study. Compliance with screening mammography was low. The major barriers that existed to achieving a higher level of compliance among the women studied were lack of physician recommendation and the cost of screening mammograms.

**KEYWORDS:** Breast cancer, breast cancer screening, compliance, mammogram, breast self-examination, clinical breast examination.
